### ABSTRACT

The diabetic foot (DF) is a major public health problem, with infection of the DF being a major risk factor for amputation. This study aimed to establish the bacteriological profile of diabetic foot infection and to evaluate the resistance of isolated bacteria to antibiotics. Retrospective study of 150 patients in the internal medicine departments of the University Hospital of Batna, the University Hospital of Constantine and the EPH of Oum El Bouaghi, over 24 months from September 2019 to August 2021. The population had an average age of  $46 \pm 13$  years and a sex ratio of 1.88 in favour of men. The majority of patients were type 2 diabetics with a mean duration of the evolution of 20 years. The starting point of the foot lesions was inter-toe intertrigo and trauma. The most frequent lesion found was an infectious lesion followed by gangrene, classified in 33.64% of cases as Grade 2 according to Wagner. We performed a swab of the ulcer, and direct examination showed a predominance of Gram-negative bacilli (GNB) in 78.56% of the samples, 17 different bacterial species were isolated, predominantly *Escherichia coli* and *Pseudomonas aeruginosa*. We studied the antibiotic resistance of the most frequently isolated bacteria, the antibiotic therapy was initially probabilistic and then adapted to the antibiogram. The multidisciplinary management of diabetic foot is still very precarious, and the best treatment is prevention.

### Introduction

Regardless of the type, diabetes can lead to complications that affect several parts of the body and increase the overall risk of premature death. Acute complications include ketoacidosis, hyperosmolar coma, hypoglycaemia, and chronic complications include diabetic nephropathy, neuropathy and retinopathy, chronic infections and diabetic foot.

Several factors contribute to the development of foot ulcers in diabetic patients; peripheral neuropathy and vascular insufficiency (1). In addition to these two factors, a third factor is a bacterial infection, which can set in; infection of a diabetic foot ulcer multiplies the risk of amputation by a factor of 10 (2). It accounts for about a quarter of hospital admissions in diabetic patients (3). The rate of lower limb amputations in diabetics is more than 40 times higher than in non-diabetics (4). It is also a significant cause of unjustified antibiotic therapy and as such contributes to the increase in bacterial resistance and its spread through care. It is therefore essential to know the bacterial ecology of diabetic foot infections in healthcare institutions to allow adequate management and optimal use of antibiotics, with the hope of reducing the risk of amputation and the emergence of multi-resistant bacteria. Our study aims to analyse the bacteriological profile of diabetic feet managed in the internal medicine departments of the University Hospital of Batna, the University Hospital of Constantine and the EPH of Oum El Baouaghi and its influence on the first-line antibiotic therapy.

### Materials and Methods

#### Study population and conducting and carrying out the survey

This was a retrospective descriptive and analytical study of the management of the diabetic foot carried out over a 24-month period from September 2019 to August 2021. Out of an initial number of 200 selected patients, 150 were surveyed, our type 1 (T1D) and type 2 (T2D) diabetics were hospitalized for the diabetic foot at the level of the internal medicine departments of CHU Benflis Touhami of Batna, CHU Abdesselam Benbadis of Constantine and EPH Mohamed Boudiaf of Oum El Bouaghi Patients with or without antibiotic therapy and the different aspects and stages of foot infection were included in our study. Patients with gestational diabetes and non-diabetic patients with foot lesions or amputations were excluded from the study.

Information on the patients surveyed was collected by means of a validated questionnaire including epidemiological, clinical, para-clinical and therapeutic data (age, sex, type of diabetes...).

#### Pre-clinical examination

##### Bacteriological sampling phase

The sampling method used is superficial, rarely deep pus swabbing, which consists of rubbing the surface of the lesion in a zigzag movement combined with rotation using two sterile swabs; one for direct microscopic examination and the other for culture. The samples are then rapidly sent

\* Corresponding author. Email: [s.fetni@univ-batna2.dz](mailto:s.fetni@univ-batna2.dz)

to the microbiology laboratories of the CHU of Constantine, the EPH-Sanatorium of Batna and the EPH of Oum El Bouaghi.

### Microbiological analysis phase

Once the samples arrived at the laboratories, a series of bacteriological analyses were carried out: direct examination, culture and biochemical characterisation of the bacterial strains. We studied the sensitivity to antibiotics of the different germs isolated.

### Statistical analysis

The results were presented as percentages. All calculations were performed using SPSS version 20.00.

## Results

### General description of the survey population

We included 150 patients admitted for diabetic foot, the average age was  $46 \pm 13$  years with a clear male predominance in more than 65% of cases with a sex ratio of 1.88. Type 2 diabetes represented more than 91% of cases with the presence of familial diabetes of maternal origin in 84.13% of cases. Type 2 diabetes accounted for more than 91% of the cases, with the presence of familial diabetes of maternal origin in 84.13% of cases. The average duration of diabetes was 20 years [2 to 35 years]. More than 54.85% of the patients were on insulin, only 13.62% were on oral antidiabetic drugs (OADs), and both treatments were associated with 31.53%.

All our patients had at least one degenerative complication, including 54.26% diabetic neuropathy (DN), 16.54% diabetic retinopathy and 29.2% nephropathy. 48.96% had suffered a stroke, 29.54% a transient ischaemic attack (TIA) and 21.50% had angina. In our series, hypertension was found in 64.12% and 71.28% of our patients were smokers.

In our study, previous amputation for diabetic foot lesions was found in 34.15% of our patients, 65.85% had not undergone amputation, trauma was found in 10.44% of patients, wearing inadequate footwear was mentioned by 1.40% and inter-toe intertrigo (ITI) was present in 5.81% of our patients (Tables 1 and 2).

### Clinical data

In our study, the right foot was most frequently affected with 48.21% of cases, with 27.32% of cases involving the leg, 9.33% of cases involving gangrene and 8.01% of cases involving a wound. 33.64% of the lesions were classified as Grade 2 according to Wagner. The association of clinical signs in favour of infection was found in 75.33% of patients, notably heat (16.84%), oedema (66.85%) and foul odour (96.85%). NP was found in 16.02% of our patients, it was represented by paresthesia/dysesthesia in 42.85%, hyperkeratosis in 33.02%, and skin dryness in 30.92% of cases. Arteriopathy was found in 8.64% of patients, characterised by the abolition of peripheral pulses in 23.56% of cases, pallor (22.85%) and coldness (28.94%) and trophic disorders in 24.65% of patients (Table 3).

### Para-clinical data: Radiology and microbiology

X-rays of the foot were performed in 64 patients, with 55.69% showing osteitis, 22.85% erosion, 18.94% bone lysis and 2.52% a geode. Angiography was performed

on 51 patients. Magnetic resonance imaging (MRI) and computed tomography (CT) were performed on 16 and 19 patients respectively. Arteriography was performed in 51 patients (Table 4).

The microbial culture was sterile in 18 cases (11.84%), mono-microbial in 73 cases (48.93%) and poly-microbial in 59 other cases (39.23%). 17 different bacterial species were isolated, and their distribution by the family showed the predominance of enterobacteria which represented 40.82% of the isolates, followed by staphylococci (21.25%), streptococci (20.06%) and non-fermenting BGN with a rate of 17.90%. The distribution by species showed the predominance of *Escherichia coli* (20%), *Pseudomonas aeruginosa* (15.33%) then *Staphylococcus aureus* and *Klebsiella pneumoniae* (10.66%). We studied the bacterial resistance of the most frequently isolated species (Tables 4, 5, 6a, 6b and 6c).

## Discussion

In our study, the mean age was  $46 \pm 13$  years which differs from the results of Mezhoud et al., 2018, who found 65 years (5), Salah, 2018, reports 68 years (6) and Laidi et al, reported 56 years of age (7), with a sex ratio of 1.88 in favour of men, which is consistent with the results of a study conducted in Morocco (Casablanca) which was 2 (7), Turkey (2.2) (8), Ivory Coast (1.6) (9). 91% of our patients were type 2 diabetics, which is consistent with the results of a study conducted in Oran (Algeria) 92.11% (10), Morocco 89% (7), Togo 88.7% (11), Congo 86.2% (12). The mean duration of diabetes was 20 years, which was far from the results found by Faraoun et al., 2013, (14.26 years) (10). Bah et al, 2015, (15 years) (13), El Allali, 2015, in Rabat (Morocco) 12.56 years (14), Kourichi et al, 2018, (16.31 years) (15). 54.85% of our patients were on insulin, similar results reported by El Allali B, 2015, 59% (14) and Mezhoud et al., 2018, 59% (5).

In our series, hypertension was found in 64.12% of patients. While the study conducted at the University Hospital of Bejaia in 2018 showed that hypertension was present in 47.62% of patients (15), Awalou et al., 2018, found 41.9% (11), Tadili et al., 2008, reported that 49% of patients were hypertensive (16).

Right foot involvement was the most frequent with 48.21% of cases. This differs from the results of the study by Kourichi et al, 2018, where the frequencies of involvement of the right and left feet were close (47.62% and 38.09% respectively), and the bilaterality of the lesions was noted in 14.28% of cases (15). As well as those noted at the University Hospital of Oran with the same involvement of both sides at 45.11%, and bilateral involvement at 0.78% (10).

In our study, the infectious lesion was the most frequently found in 49.33% of patients, gangrene in 9.33%, which differs from the values found in the study of Awalou et al., 2018 (11) and those of the study of Bah et al, 2015 (13), with a predominance of Grade 2 lesions, while in the study by Awalou et al, 2018 (11), Grade 5 was predominant and in the study by Hering et al, 2010, Grade 3 was predominant (17).

The cultures were mono-microbial in 48.93% of cases and poly-microbial in 39.23% of cases. This is consistent with the results reported by Turhan et al, 2013, and Richard et al, 2011, who found that mono-microbial cultures

**Table 2.** Distribution of the population according to risk factors and etiology of PD.

| Characteristic                               | Values (n=150) |
|--|----------------|
| <b>FDR and etiology of PD</b>                |                |
| Infection                                    | 19 (12.36%)    |
| IIO  | 9 (5.81%)      |
| Trauma                                       | 16 (10.44%)    |
| Neuropathy                                   | 49 (32.54%)    |
| Arteriopathy                                 | 36 (24.23%)    |
| Burns  | 4 (2.58%)      |
| Skin mycoses                                 | 6 (4.18%)      |
| Onychomycosis                                | 5 (3.58%)      |
| Ingrown nails                                | 4 (2.88%)      |
| Inadequate footwear                          | 2 (1.40%)      |
| <b>Type of shoes</b>                         |                |
| Slippers                                     | 19 (12.56%)    |
| Sandals                                      | 16 (10.58%)    |
| Espadrilles                                  | 24 (16.12%)    |
| Shoes  | 45 (30.04%)    |
| Barefoot                                     | 46 (30.70%)    |
| <b>Reasons for consultation</b>              |                |
| Pain   | 6 (3.97%)      |
| Wound  | 17 (10.85%)    |
| Infection                                    | 25 (16.54%)    |
| Ulcer  | 15 (9.82%)     |
| Paresthesia                                  | 21 (14.25%)    |
| Osteitis                                     | 40 (26.58%)    |
| Gangrene                                     | 17 (11.23%)    |
| Trophic disorders                            | 6 (4.25%)      |
| Screening                                    | 4 (2.51%)      |
| <b>Knowledge of foot risk</b>                |                |
| <b>Foot hygiene</b>                          |                |
| Good   | 19 (12.58%)    |
| Average                                      | 68 (45.57%)    |
| Wrong  | 63 (41.85%)    |
| <b>What to do in case of a wound injury?</b> |                |
| Self-medication                              | 43 (28.34%)    |
| Consultation of a GP                         | 49 (32.89%)    |
| Traditional medicine                         | 58 (38.77%)    |

**Table 3.** Distribution of clinical signs in our patients.

| Clinical signs  | Numbers and %.      |
|---|---------------------|
| <b>Foot damage</b>                                    |                     |
| Right   | 72 (48.21%)         |
| Left  | 19 (12.65%)         |
| Bilateral   | 59 (39.14%)         |
| <b>Classification of injuries according to Wagner</b> |                     |
| G1  | 43 (28.41%)         |
| G2  | 50 (33.64%)         |
| G3  | 48 (32.03%)         |
| G4  | 7 (4.85%)           |
| G5  | 2 (1.07%)           |
| <b>Aetiological forms</b>                             |                     |
| <b>Infection</b>                                      |                     |

predominated (8, 18).

The medical literature reports that diabetic foot infections are dominated by Gram-positive bacteria (GPB) (18-19). However, this predominance is not universal as recent studies from African and Asian countries have reported the predominance of Gram-negative bacteria (GNB) in diabetic foot infections (20-21, 8). In our series, the predominant pathogen was *Escherichia coli* (20%), which is consistent with the findings of Ako-Nai et al, 2006, in Nigeria (21) and Durgad et al, 2014, in India (20) (Table 7).

In our study, PMBs expressed a relatively low level of resistance to penicillin, cefoxitin, oxacillin and gentamicin. Ciprofloxacin, ofloxacin, fusidic acid, vancomycin and tetracycline were the most active antibiotics. Vancomycin was active on all staphylococci; *Staphylococcus aureus* was sensitive to rifamycin and pristinamycin, *Staphylococcus hominis* was sensitive to teicoplanin.

In the study by Turhan et al, 2018, vancomycin was

active on all PMBs. Fusidic acid was active on all staphylococci, including methicillin-resistant strains (8). Fusidic acid could therefore be a good alternative in the treatment of diabetic foot infections.

In the study by Al Benwan et al, 2012, vancomycin was active on all PMBs. In contrast, staphylococci expressed a high rate of resistance to fusidic acid which was 42% (25).

Regarding BGN, the Enterobacteriaceae strains isolated in our study expressed a relatively low level of resistance to erythromycin, ticarcillin, amikacin and cefazolin. Fusidic acid, ciprofloxacin, cefepin and chloramphenicol were the most active antibiotics; amoxicillin was active on all PMBs except *Escherichia coli*.

In studies by Turhan et al, 2018, et al. Benwan et al, 2012, imipenem, amikacin and piperacillin-tazobactam were the most active antibiotics on BGN. These bacteria expressed a high rate of resistance to ampicillin, amoxicillin-clavulanic acid and ciprofloxacin (8, 19, 25).

**Table 7.** Bacteriological data of diabetic foot infections.

| Author of the study (year)        | Country                | BGN    | BGP    | Predominant pathogen (rate)  |
|-----------------------------------|------------------------|--------|--------|--|
| Ako-Nai et al. (2006) (21)        | Nigeria                | 58%    | 33%    | <i>Escherichia coli</i> (15.1%)  |
| Richard et al. (2011) (18)        | France                 | 36%    | 60%    | <i>Staphylococcus aureus</i> (32.5%)                                     |

Diabetic foot is a frequent complication of diabetes, silent but serious in its mortality, morbidity and disability. Its cost is among the highest of the degenerative complications of diabetes. Diabetic foot infections remain a formidable complication of diabetes. They are the main cause of hospitalisation for diabetics and one of the major causes of lower limb amputation. The diabetic foot requires multi-disciplinary management (prevention, screening, medical and surgical treatment) involving: nurses, general practitioners, diabetologists, orthopaedic and vascular surgeons, physical physicians and psychologists as well as paramedical staff.

### Conflicts of interest

The authors declare that they have no conflicts of interest.
